

# The Long-Term Decline of the U.S. Job Ladder

Aniket Baksy, University of Melbourne

Daniele Caratelli

Niklas Engbom, New York University & NBER

Workshop of the Australasian Macroeconomics Society, November 2025

# Motivation: 40 years of wage stagnation

- ▶ Real wages for average American worker have stagnated over past 40 years. **Why?**
  - ▶ technological change Autor-Levy-Murnane '03, Acemoglu-Autor '11, Acemoglu-Restrepo '20
  - ▶ globalization and trade Elsby-Hobijn-Sahin '13, Autor-Dorn-Hanson '13
  - ▶ institutional changes Autor-Manning-Smith '16, Vogel '23
- ▶ **This Paper:** Job ladder model to study role of **changing structure of labour market**
  - ▶ **Mismatch** between open jobs & searching workers
  - ▶ **Employer concentration** limiting job shopping
  - ▶ **less search by employed workers**
- ▶ These factors combine to **reduce upward job mobility** Topel-Ward '92

# Motivation: 40 years of wage stagnation

- ▶ Real wages for average American worker have stagnated over past 40 years. **Why?**
  - ▶ technological change Autor-Levy-Murnane '03, Acemoglu-Autor '11, Acemoglu-Restrepo '20
  - ▶ globalization and trade Elsby-Hobijn-Sahin '13, Autor-Dorn-Hanson '13
  - ▶ institutional changes Autor-Manning-Smith '16, Vogel '23
- ▶ **This Paper:** Job ladder model to study role of **changing structure of labour market**
  - ▶ **Mismatch** between open jobs & searching workers
  - ▶ **Employer concentration** limiting job shopping
  - ▶ **less search by employed workers**
- ▶ These factors combine to **reduce upward job mobility**  $\sim 40\%$
- ▶ Why you should care: combined effect leads to **4 p.p. lower real wages**
  - ▶  **$\approx 40\% \text{ of fall}$**  in aggregate labor share!

## Outline

- ▶ A simple job ladder model: illustrate how to infer mobility from wages
- ▶ Take simple model to data: Substantial decline in upward mobility
- ▶ Direct evidence: slower wage growth from job mobility in NLSY over time
- ▶ Full model: add features of data, labour market frictions
- ▶ Quantitative results: role of declining mobility for wages

## A Simple Job Ladder Model

- ▶ Time is continuous, infinite horizon, focus on steady states
- ▶ Unit mass of risk-neutral workers move in and out of employment & across jobs
- ▶ While non-employed, receive **job offers** at rate  $\lambda$ 
  - ▶ an offer = a piece rate  $w$  drawn from a **wage offer distribution  $F(w)$**
  - ▶ assume parameters such that non-employed worker accepts all offers
- ▶ While employed, demographics  $x \implies Z(x)$  efficiency units of labour
  - ▶ earn wage  $w$  per efficiency unit supplied for as long as she is employed in the job
  - ▶ Job ends for three possible reasons:
    1. **Outside offers** at rate  $\phi\lambda$  with a wage from  $F(w)$  that she **may** accept
    2. **Reallocation Shocks** at rate  $\delta\lambda^f$  with a wage from  $F(w)$  that she **must** accept
    3. **Job Loss Shocks** at rate  $\delta(1 - \lambda^f)$  that leave her non-employed

# A Simple Job Ladder Model

- In steady state, the share of non-employed workers  $u$  satisfies **flow balance**

$$\underbrace{\lambda u}_{\text{job finding} = \text{outflows from } u} = \underbrace{\delta(1 - \lambda^f)(1 - u)}_{\text{job loss} = \text{inflows to } u}$$

- Let  $G(w)$  = CDF of wages. In steady state, satisfies **Kolmogorov Forward Equation**

$$0 = -\underbrace{\delta G(w)}_{\text{reallocation (out)} + \text{job loss}} + \underbrace{\lambda F(w) \frac{u}{1 - u}}_{\text{hires from non-empl.}} - \underbrace{\phi \lambda (1 - F(w)) G(w)}_{\text{outside offers}} + \underbrace{\delta \lambda^f F(w)}_{\text{reallocation (in)}}$$

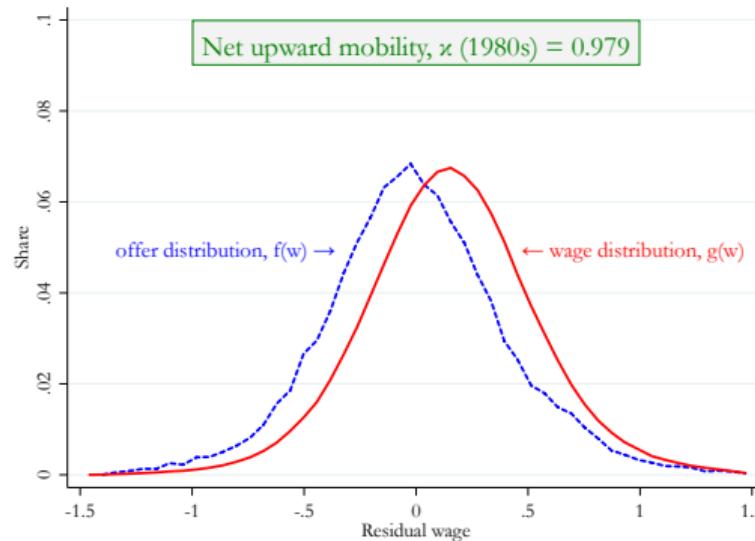

# Net Upward Mobility is All You Need

- Rearrange KFE + use flow balance to obtain

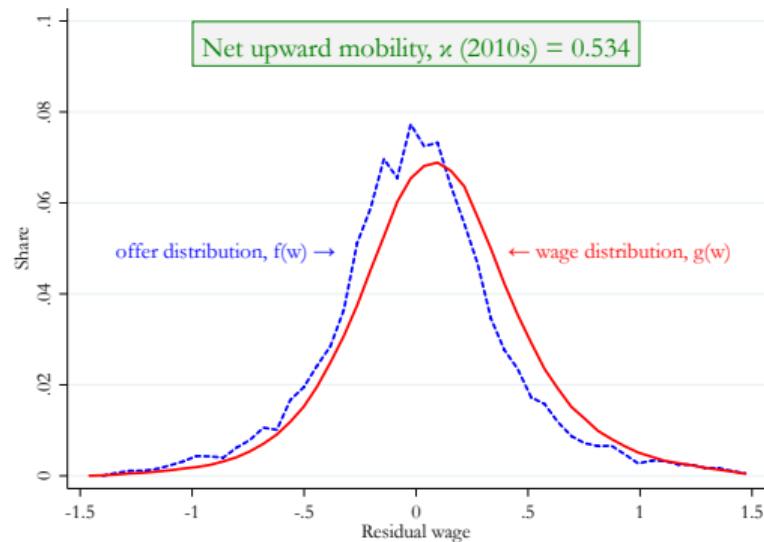

$$G(w) = \frac{F(w)}{1 + \kappa(1 - F(w))}, \quad \underbrace{\kappa}_{\text{net upward mobility rate}} \equiv \frac{\phi\lambda}{\delta}$$

- Net upward mobility rate,  $\kappa$  = Average # of outside offers between two separation events
- Higher  $\kappa \implies$  Faster wage growth  $\implies$  larger gap btw offer & wage distributions
- What does  $\kappa$  look like in data? Using CPS, obtain residual wages ▶ details
- Estimate  $G(w)$  and  $F(w)$  non-parametrically
  - Wage distribution  $G(w)$ : residual wages among all workers
  - Offer distribution  $F(w)$ : among those who were non-employed in the previous month

# The Offer and Wage Distributions

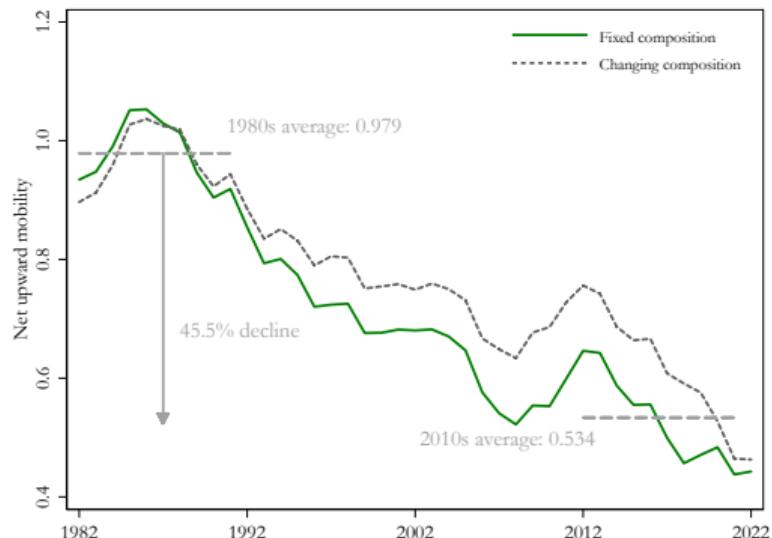

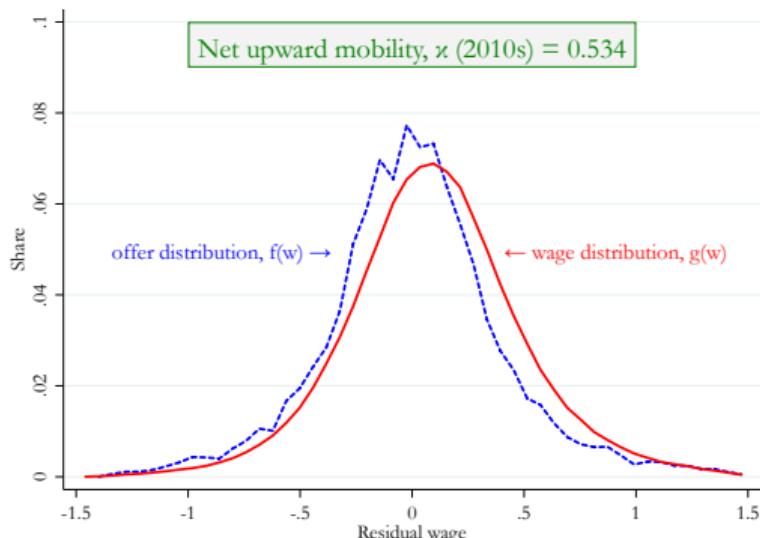

# The Offer and Wage Distributions

# The Offer and Wage Distributions

**40-50% decline in net upward mobility between the 1980s and 2010s**

by demographic groups

► Overid test

► Between-occupation

► Better Matched?

► Direct Evidence (CPS, PSID)

## Direct Evidence on Wage & Employment Dynamics

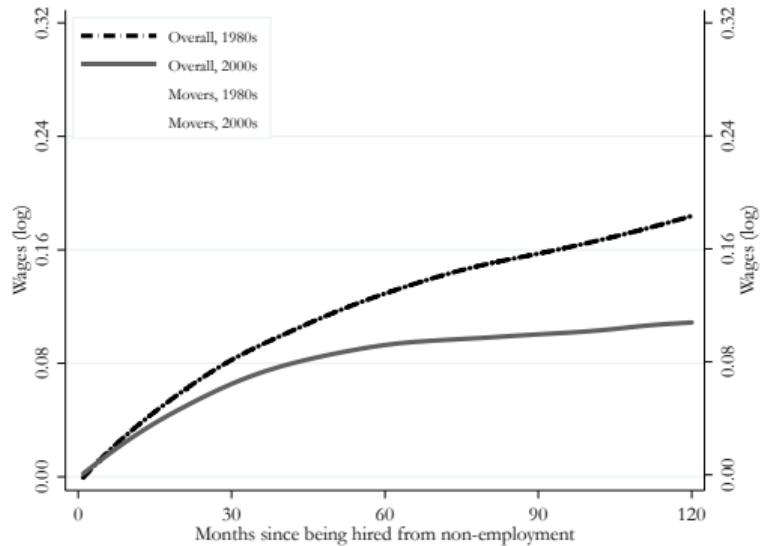

- ▶ Ideal data set contains employment & wage dynamics
- ▶ Monthly frequency individual-level panel data from NLSY
  - ▶ NLSY 1979 was aged 14–22 in 1979, has been followed annually (bi-annually since 1994)
  - ▶ NLSY 1997 was aged 12–17 in 1997, has been followed annually (bi-annually since 2014)
- ▶ We study wage growth for up to 120 months post a non-employment spell
  - ▶ Residualize wages (indiv FE + deflate with average residual wages of same age)
  - ▶ Decompose wage growth: due to job mobility, stayer wage growth, flows in/out of non-emp

▶ wage distributions

▶ decomposition formula

# Less Wage Growth from Upward Job Mobility

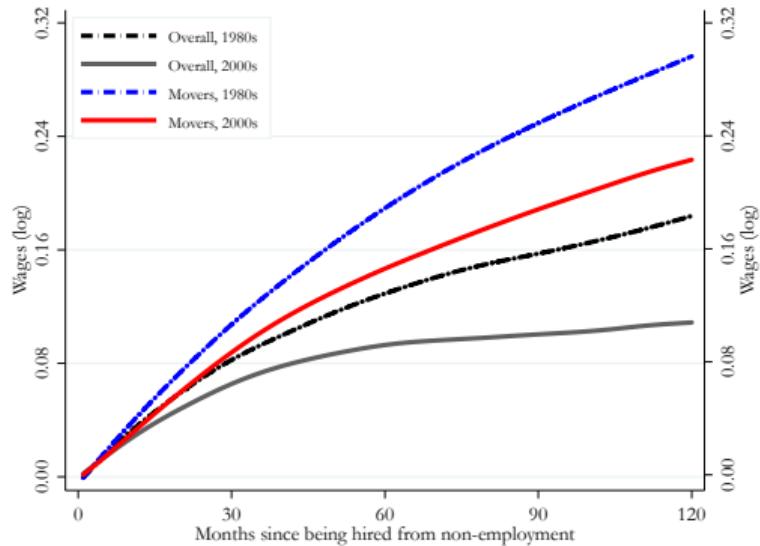

Wage growth after hire from non-employment

NLSY '97 sees much slower wage growth  
after hire than NLSY '79

# Less Wage Growth from Upward Job Mobility

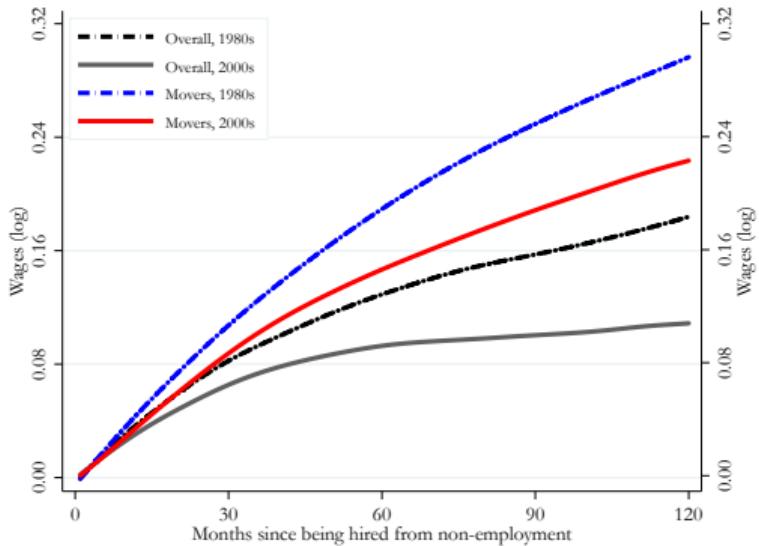

Wage growth after hire from non-employment

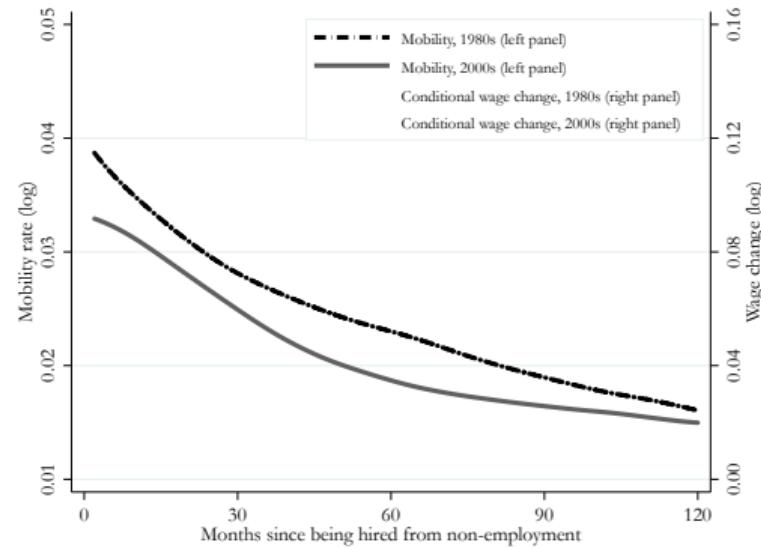

driven by slower wage growth of **movers** in  
NLSY '97 than NLSY '79

# Less Wage Growth from Upward Job Mobility

Wage growth after hire from non-employment

Frequency of mobility & conditional wage gain

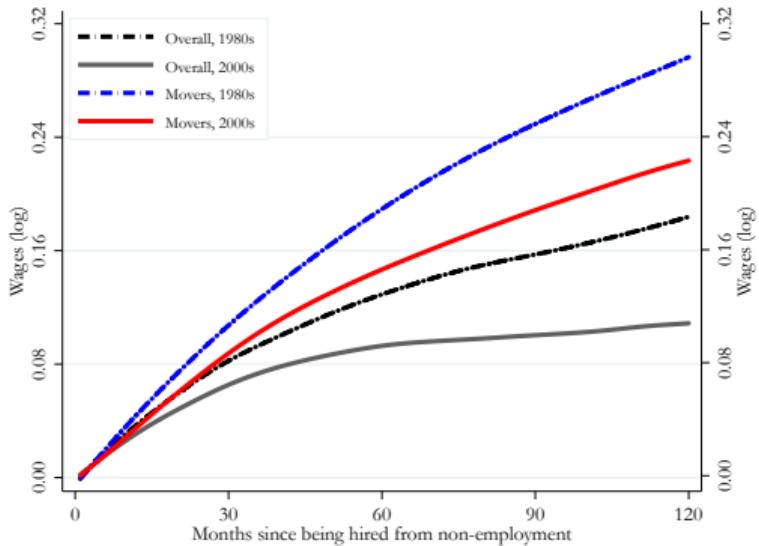

driven by slower wage growth of **movers** in  
NLSY '97 than NLSY '79

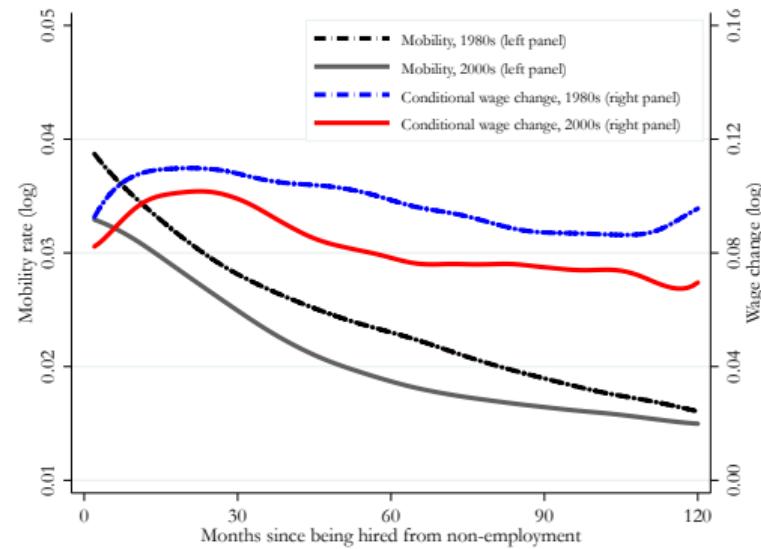

driven by both slower mobility rates

# Less Wage Growth from Upward Job Mobility

Wage growth after hire from non-employment

Frequency of mobility & conditional wage gain

driven by slower wage growth of **movers** in  
NLSY '97 than NLSY '79

driven by both slower mobility rates and by  
lower wage growth for movers

## Full Model: Overview

- ▶ Extension 1: on-the-job wage dynamics
- ▶ Extension 2: unobserved heterogeneity
- ▶ Extension 3: respondent error in CPS data

## Full Model: Overview

- ▶ Extension 1: on-the-job wage dynamics
  - ▶ Wages evolve **on-the-job** according to an AR1 in continuous time

▶ full model KFE

$$dw = \theta(\mu - w)dt + \sigma dW(t)$$

- ▶ Extension 2: unobserved heterogeneity
- ▶ Extension 3: respondent error in CPS data

# Full Model: Overview

- ▶ Extension 1: on-the-job wage dynamics
  - ▶ Wages evolve **on-the-job** according to an AR1 in continuous time

▶ full model KFE

$$dw = \theta(\mu - w)dt + \sigma dW(t)$$

- ▶ Extension 2: unobserved heterogeneity
  - ▶ Two **unobserved types**, different separation rates, wage growth
  - ▶ Different offer distributions,  $F^k(w)$ , differing in mean values with  $\mathbb{E}^2(w) = \mathbb{E}^1(w) + \omega$
- ▶ Extension 3: respondent error in CPS data

# Full Model: Overview

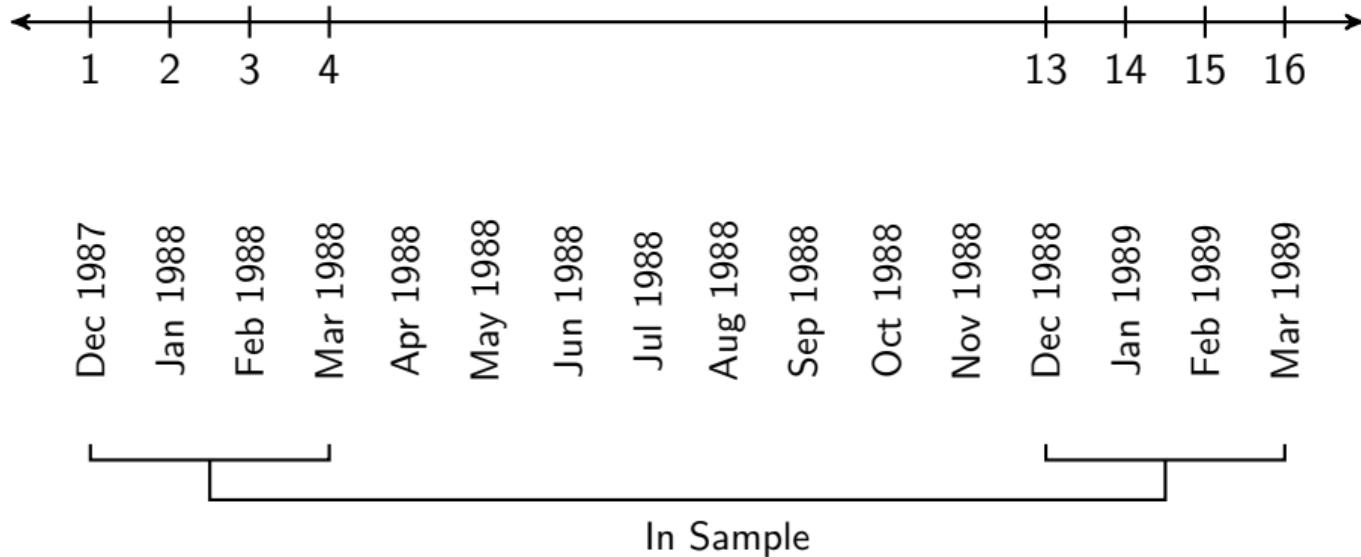

- ▶ Extension 1: on-the-job wage dynamics
  - ▶ Wages evolve **on-the-job** according to an AR1 in continuous time

▶ full model KFE

$$dw = \theta(\mu - w)dt + \sigma dW(t)$$

- ▶ Extension 2: unobserved heterogeneity

  - ▶ Hold **one/a few params** fixed in 1980s
  - ▶ Quantify impact on **gap** and hence  
overall wages = offered wages + gap
- Combined effect: -4.0p.p. real wages**  
 $\approx 40\%$  of labor share decline)

# The Structure of the U.S. Labor Market & Wage Stagnation

We use an estimated structural job ladder model to show:

1. **Upward job mobility has fallen by 40%** between the 1980s and 2010s
2. Primarily accounted for by changes in three structural factors:
  - (a) **Greater mismatch** between open jobs and searching workers
  - (b) **Greater employer concentration** that has limited the scope for job shopping
  - (c) **Less search by employed workers**
3. Combined effect: **4 p.p. lower real wages** ( $\approx 40\%$  of fall in aggregate labor share)

# Appendix

# Taking the Simple Model to Data

▶ back

- ▶ Main dataset: Current Population Survey (CPS), 1982-2023
- ▶ Theory about residual wage dispersion: project log wages on observables year-by-year

$$\ln W_{it} = \underbrace{\alpha_{ry}}_{\text{race}} + \underbrace{\alpha_{gy}}_{\text{gender}} + \underbrace{\alpha_{ey}}_{\text{education}} + \underbrace{\alpha_{sy}}_{\text{state}} + \underbrace{\alpha_{oy}}_{\text{occupation}} + \underbrace{\alpha_{my}}_{\text{survey month}} + \tilde{w}_{it}$$

- ▶ Express wages relative to hires from non-employment of same age

$$w_{it} = \tilde{w}_{it} - \underbrace{\bar{w}_{at}}_{\text{average residual wage out of non-empl.}}$$

- ▶ Estimate  $G(w)$  and  $F(w)$  non-parametrically
  - ▶ **Wage distribution  $G(w)$** : residual wages among all workers
  - ▶ **Offer distribution  $F(w)$** : among those who were non-employed in the previous month

# Net Upward Mobility has Declined Substantially

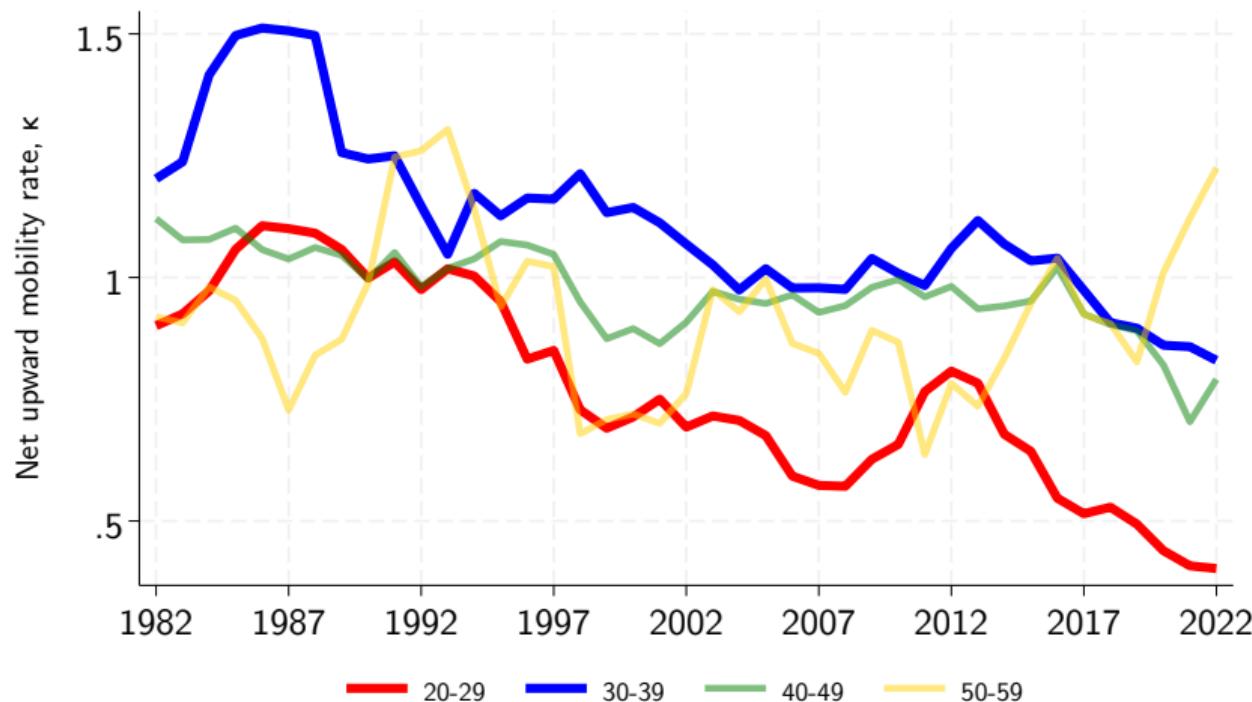

▶ back

The decline is

- ▶ larger for younger workers (20-29 and 30-39 relative to 40+) [▶ graph](#)
- ▶ similar for women relative to men [▶ graph](#)
- ▶ similar across race groups [▶ graph](#)
- ▶ larger for better educated workers [▶ graph](#)
- ▶ mixed across occupation/industry groups [▶ graph](#) & [▶ graph](#)
- ▶ largest in the middle of the occupational wage distribution [▶ graph](#)
- ▶ larger for occupations more exposed to non-competes [▶ graph](#)

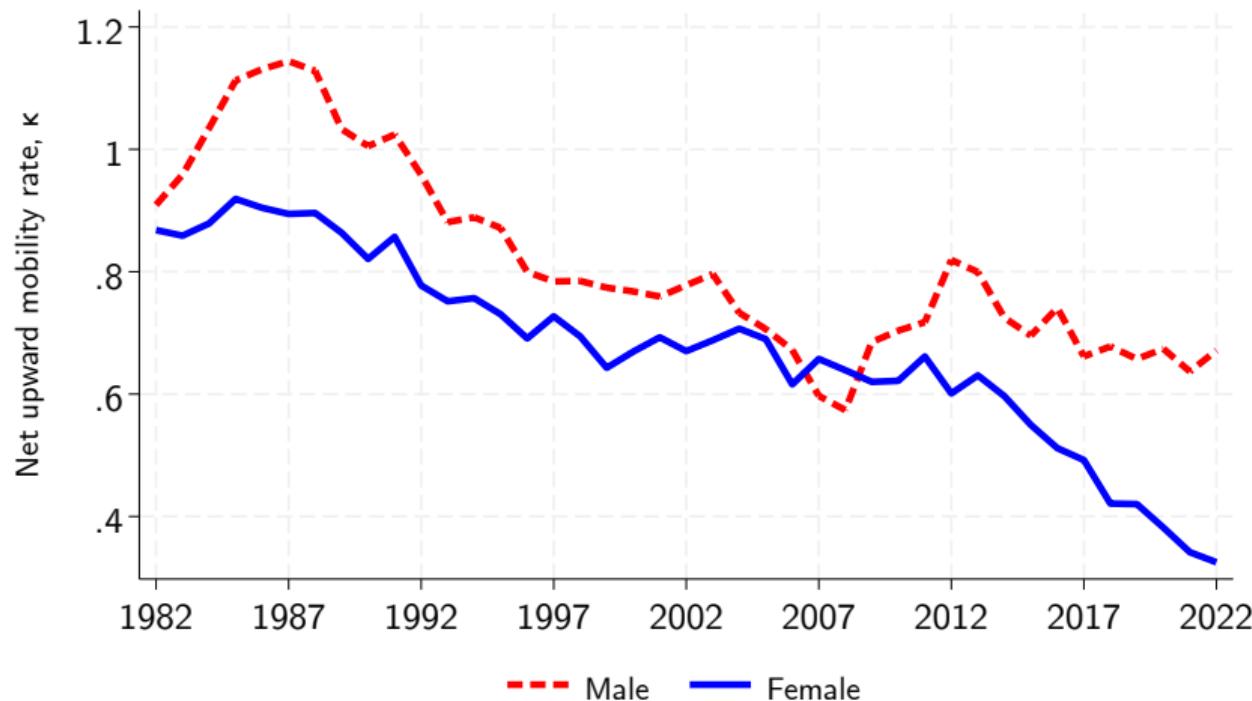

# Decline in net upward mobility sharper for the youngest

▶ back

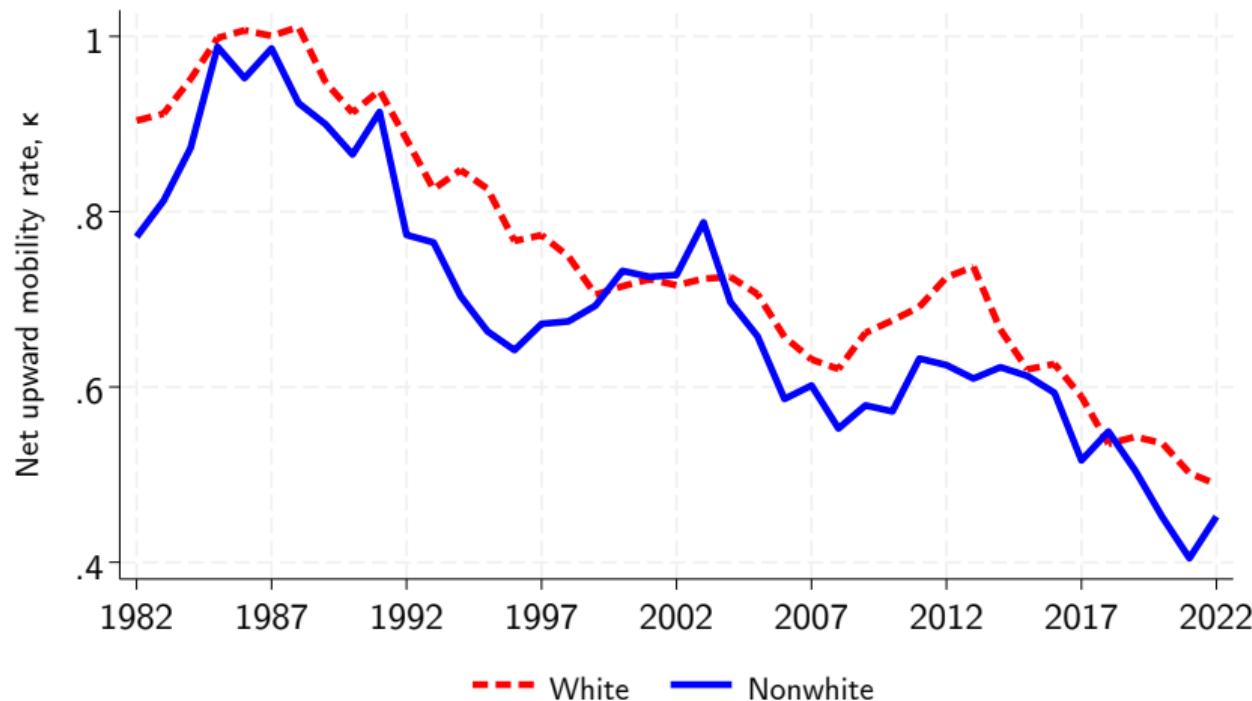

# Decline in net upward mobility comparable across genders

back

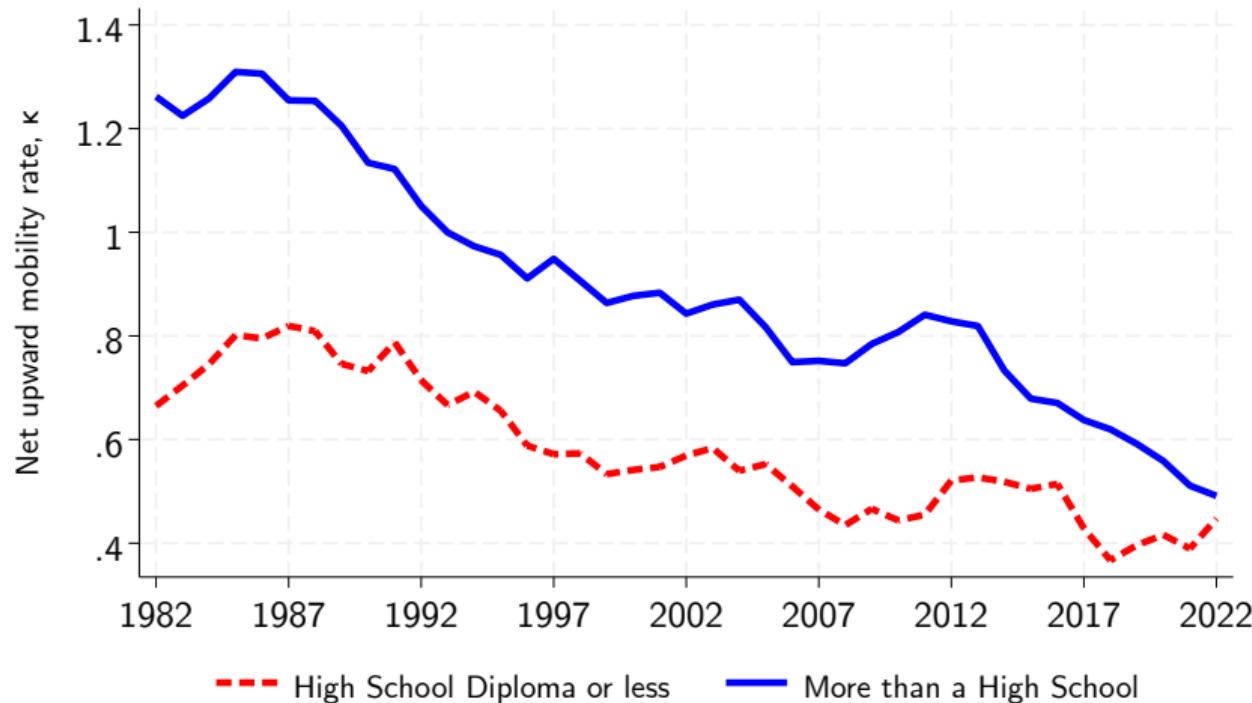

# Decline in net upward mobility similar across race groups

▶ back

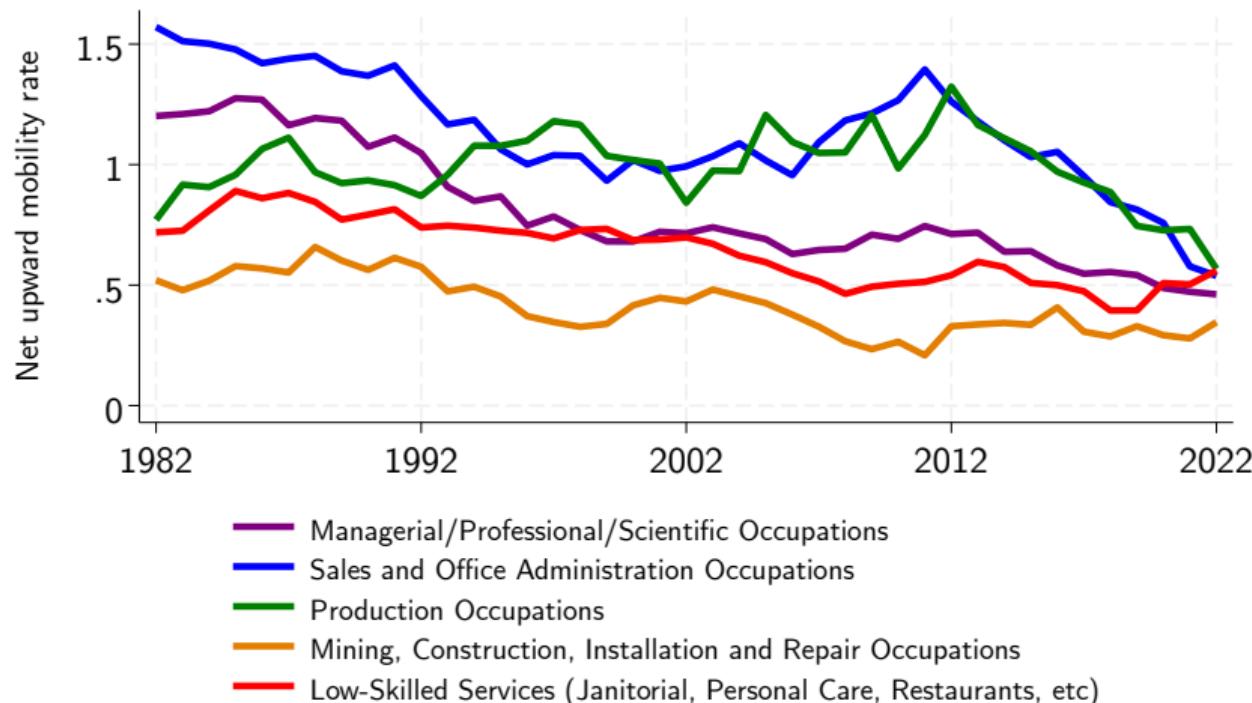

# Decline in net upward mobility larger for better educated workers

◀ back

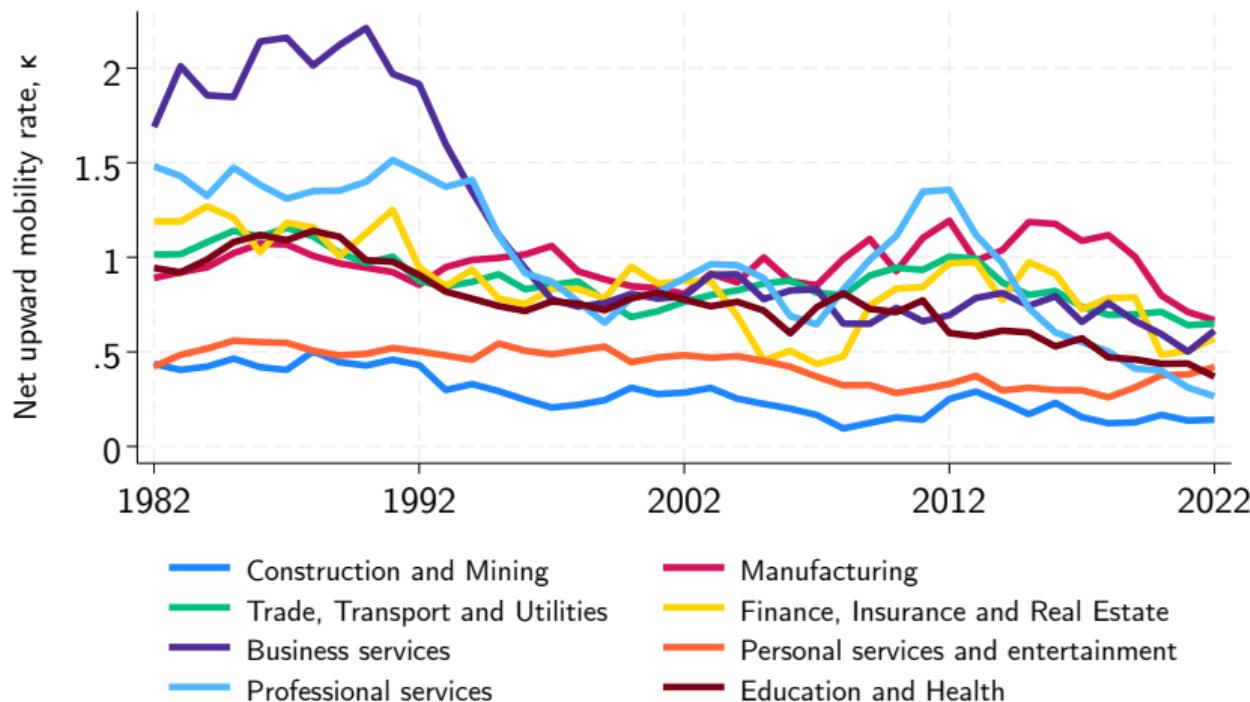

# Decline in net upward mobility mixed across Occupation groups

▶ back

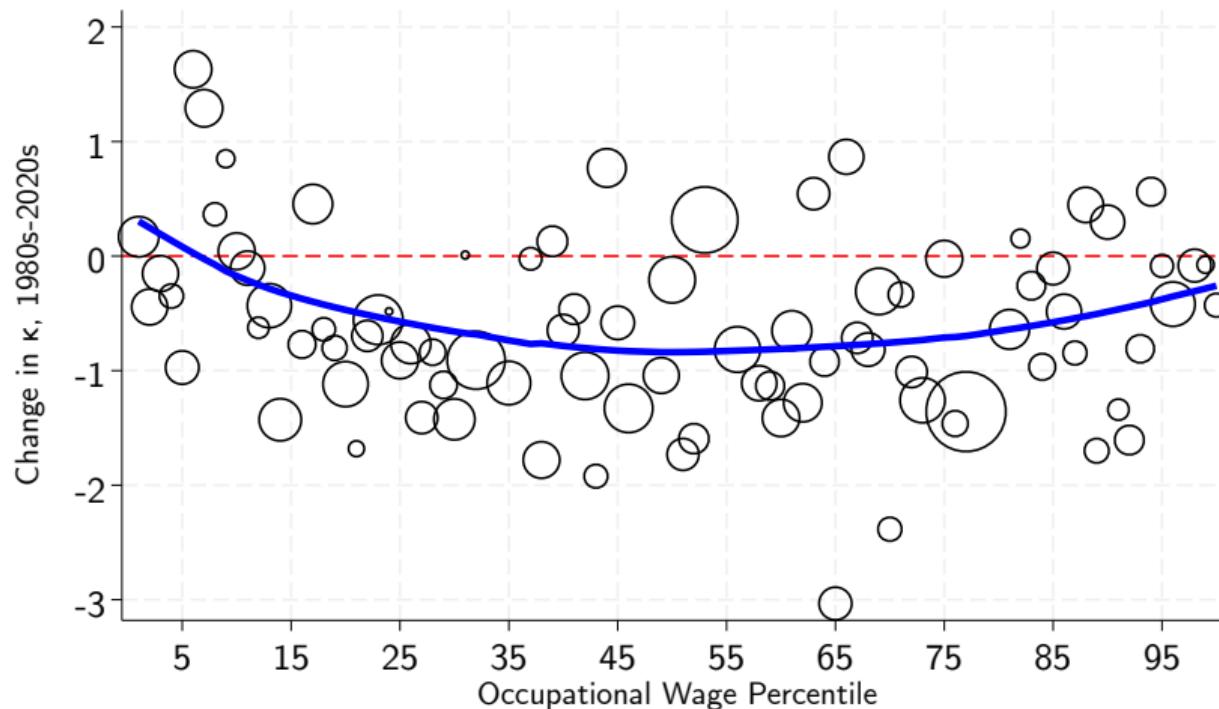

# Decline in net upward mobility mixed across Industry groups

[back](#)

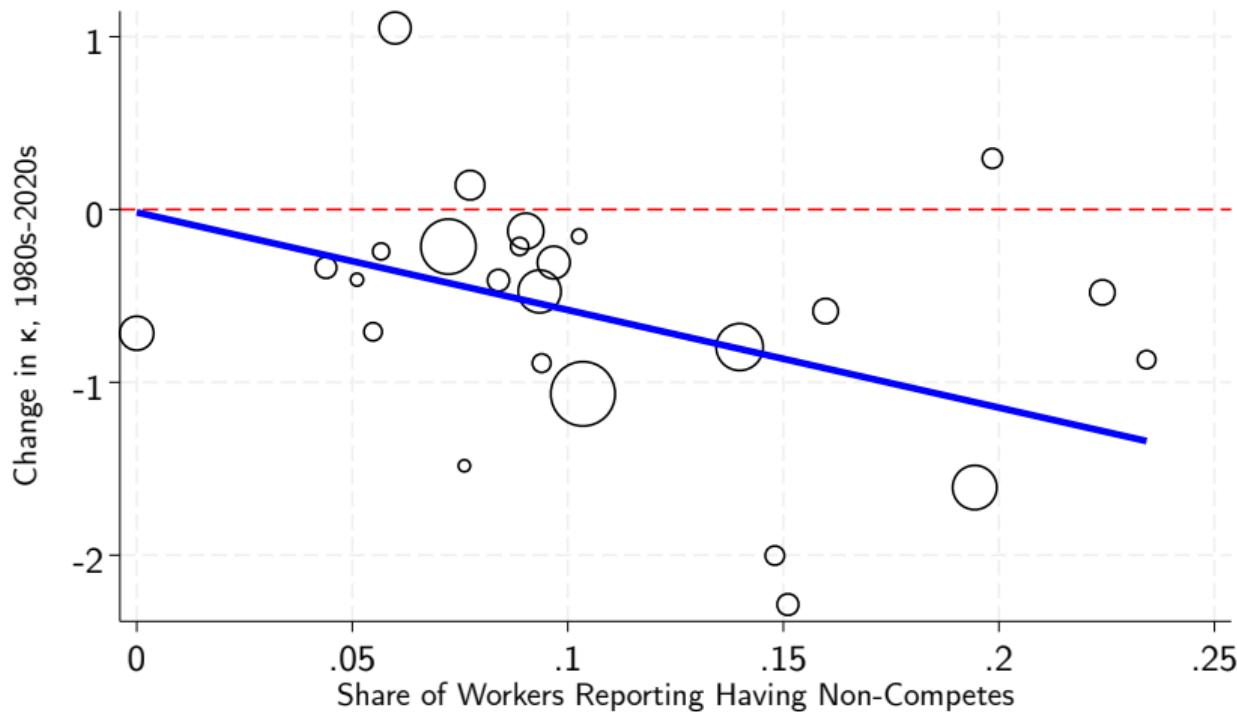

# Decline largest in the middle of Occupational Wage Distribution

## Decline larger for Occupations more exposed to Non-competes

▶ back

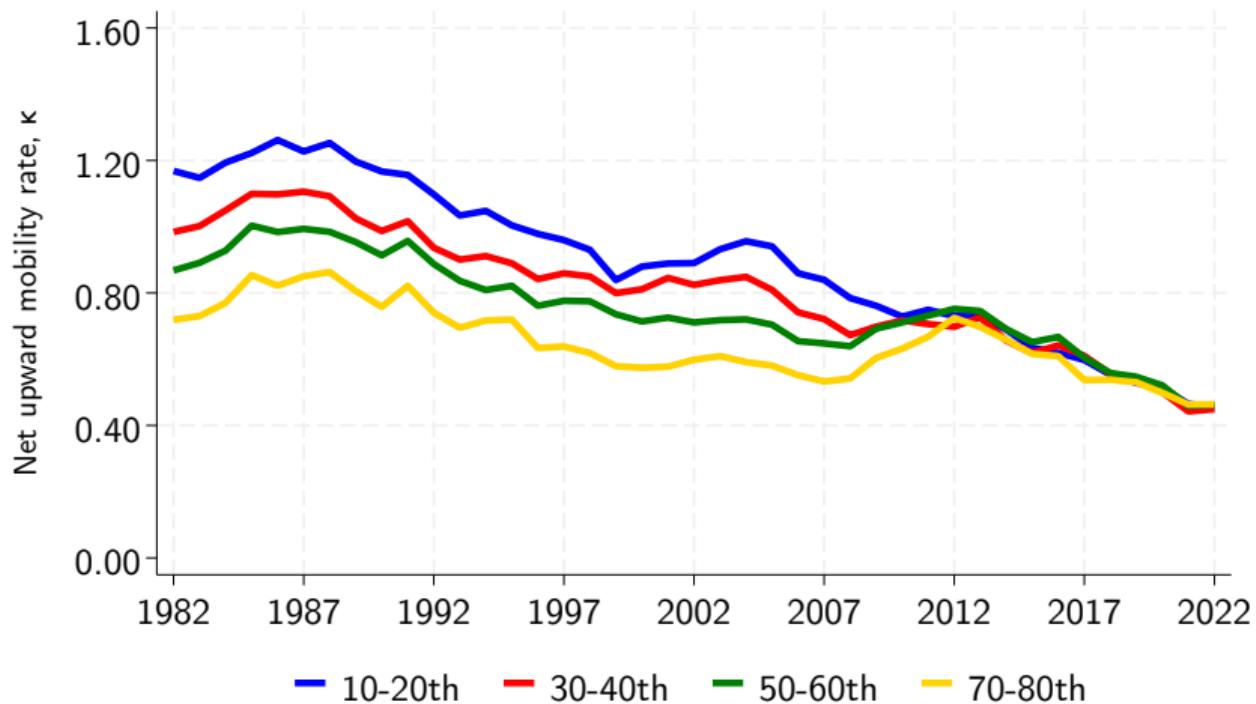

# Decline in Net Upward Mobility: $\kappa$ at Different Percentiles

▶ back

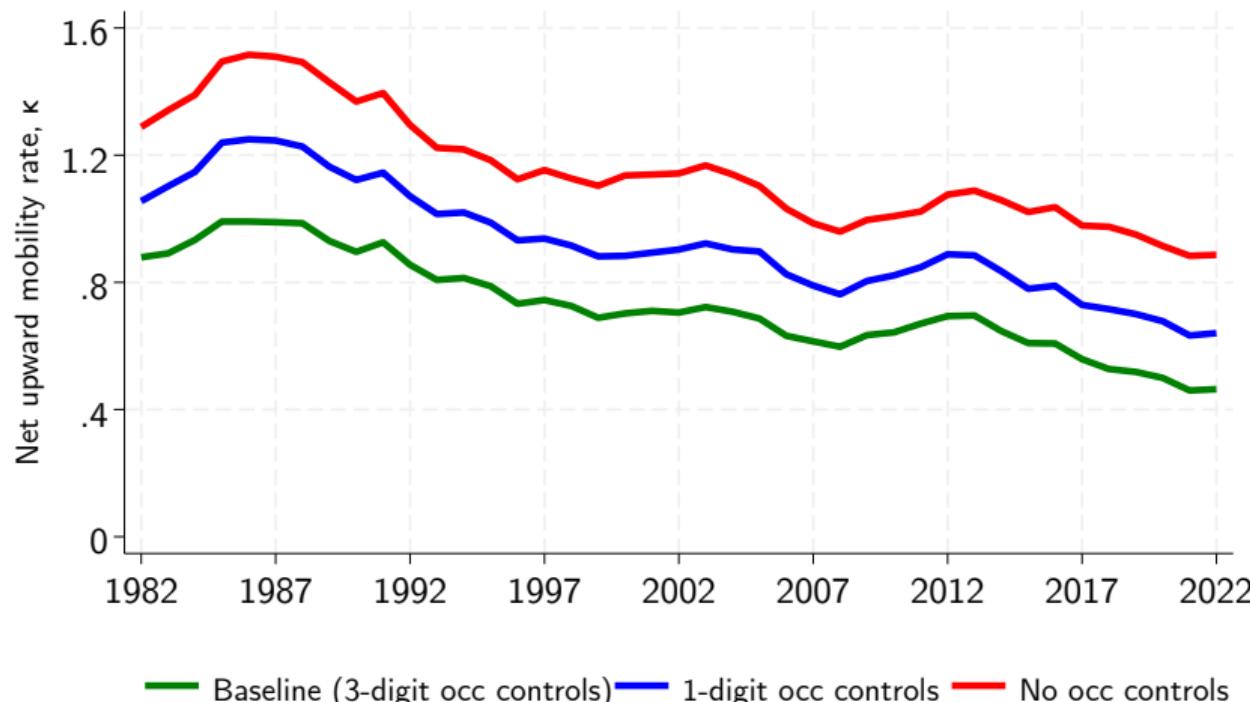

# Decline in Net Upward Mobility: $\kappa$ at Different Percentiles

▶ back

# Decline in Net Upward Mobility: Between-Occupation Results

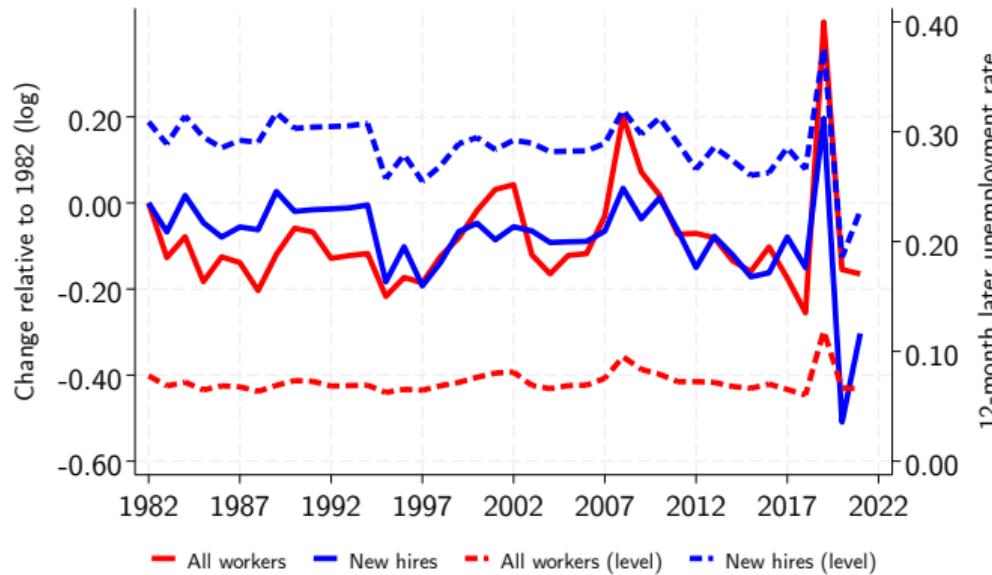

▶ back

# Decline in Net Upward Mobility: Unlikely to be better match quality

back

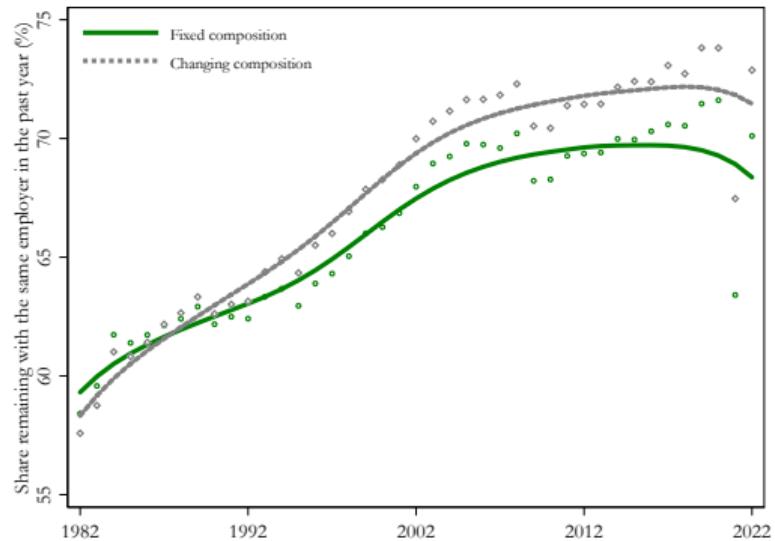

- ▶ Better screening  $\implies$  fewer bad matches form in first place
- ▶ Convergence of offer & wage distributions and fall in mobility
- ▶ However, implies decline in EN rate, especially among new matches
- ▶ Only modest decline in data

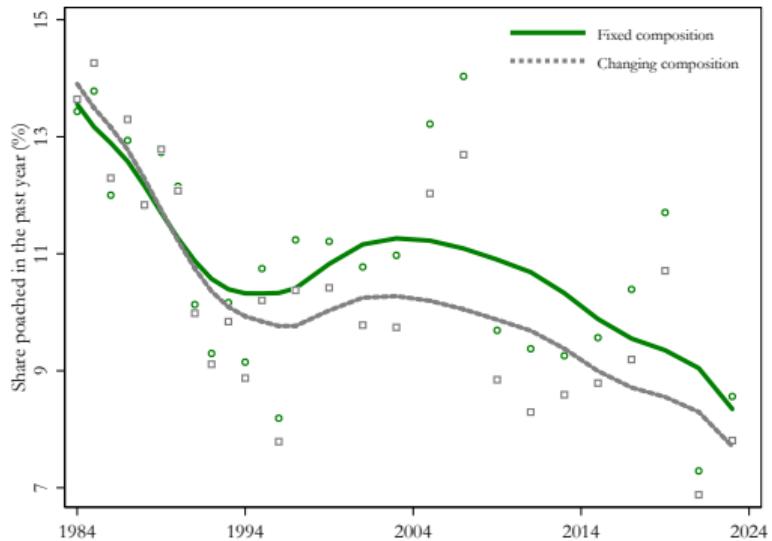

# Direct Evidence on Mobility

▶ back

March CPS: Stayed with employer throughout the year

PSID: Share of employed poached in the past year

# Decomposition of Wage Growth (NLSY)

▶ back

- Decompose residual wage growth (rel. to someone of the same age)

$$dw_t = \underbrace{\sum_{i \in S_t} \frac{\omega_{it} + \omega_{it-1}}{2} (w_{it} - w_{it-1})}_{\text{contribution of stayers}} + \underbrace{\sum_{i \in M_t} \frac{\omega_{it} + \omega_{it-1}}{2} (w_{it} - w_{it-1})}_{\text{contribution of movers}}$$
$$+ \underbrace{\sum_{i \in H_t} \omega_{it} w_{it} - \sum_{i \in X_t} \omega_{it-1} w_{it-1}}_{\text{flows in and out of non-empl.}} + \underbrace{\sum_{i \in N_t} \omega_{it} w_{it} - \sum_{i \in O_t} \omega_{it-1} w_{it-1}}_{\text{flows in and out of missing}}$$
$$+ \underbrace{\sum_{i \in S_t \cup M_t} (w_{it} + w_{it-1}) \frac{\omega_{it} - \omega_{it-1}}{2}}_{\text{adjustment factor}}$$

# NLSY vs CPS residual wage distributions

▶ back

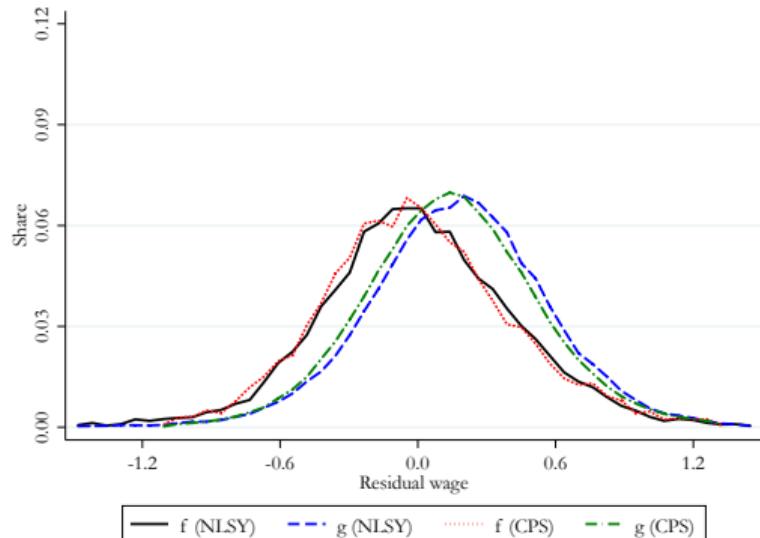

Figure: Wage and Offer Distributions in 1980s

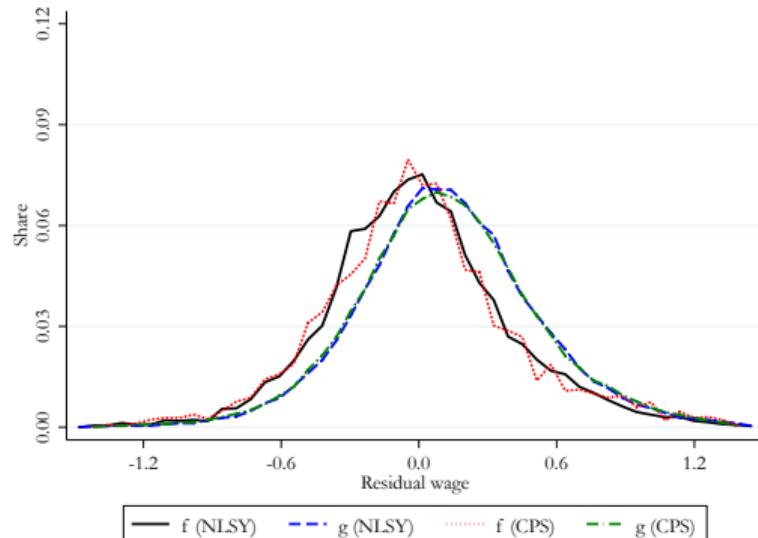

Figure: Wage and Offer Distributions in 2000s

# Wage Distributions

▶ back

- Kolmogorov Forward Equation for the wage distribution  $G(w)$  is now

$$0 = -\underbrace{\delta G(w)}_{\text{reallocation} + \text{job loss}} - \underbrace{\phi \lambda (1 - F(w)) G(w)}_{\text{outside offers}} + \underbrace{\lambda F(w) \frac{u}{1-u}}_{\text{hires from non-empl.}} + \underbrace{\delta \lambda^f F(w)}_{\text{reallocation}}$$
$$- \underbrace{\theta(\mu - w) g(w)}_{\text{drift in wages on job}} + \underbrace{\frac{\sigma^2}{2} g'(w)}_{\text{shocks}}$$

with boundary conditions  $\lim_{w \rightarrow 0} G(w) = 0$  and  $\lim_{w \rightarrow \infty} G(w) = 1$

- As before  $u$  satisfies flow balance equation

$$\lambda u = \delta (1 - \lambda^f)(1 - u)$$

# Why has mobility declined? Adding labour market structure

▶ back

- ▶ Model extension: allow  $\lambda^e$  to be determined by underlying labour market structure
- ▶ Assume US divided into perfectly segmented labour markets indexed by  $i$ 
  - ▶ Within each market,  $m_i$  identical firms each advertise  $v_i$  vacancies. Let  $V_i = v_i m_i$ .
  - ▶ On-the-job search: employed workers search w/ relative intensity  $\phi$ . Search effort  $S_i = u_i + \phi e_i$ .
  - ▶ Cobb-Douglas matching function:  $\mathcal{M}_i = \chi S_i^{1-\alpha} V_i^\alpha$
  - ▶ Firm-worker contact rate  $\lambda_i \equiv \frac{\mathcal{M}_i}{S_i} \equiv \chi x_i^\alpha$ ,  $x_i$  = tightness
  - ▶ Firms can exclude current employees from applying to own vacancies
- ▶ This setup generates two forces affecting measured aggregate mobility:
  - ▶ **Mismatch:** nonlinear matching fn + dispersion in tightness  $\implies$  lower effective agg. contact rate
  - ▶ **Concentration:** lower  $m_i \implies$  lower effective contact rates for the employed relative to non-emp

- ▶ Use the share that remain in job to get  $\lambda^f$

# Overall Mobility is Not Informative About Reallocation Mobility

◀ back

- ▶ Similar overall mobility as raw CPS
- ▶ But not informative about reallocation part
  - ▶ ≈55% are associated with wage gain
  - ▶ Systematic upward only 1/4 of total
- ⇒ Need to incorporate wage information

# Unobserved Heterogeneity is a Crucial Factor Behind the Wage-Offer Gap

▶ back

1. Job-to-job mobility toward higher paying jobs—important yet < 50% of gap
2. Unobserved heterogeneity is also very important—hires earn less in all jobs
3. Wage growth within jobs—return to tenure is positive

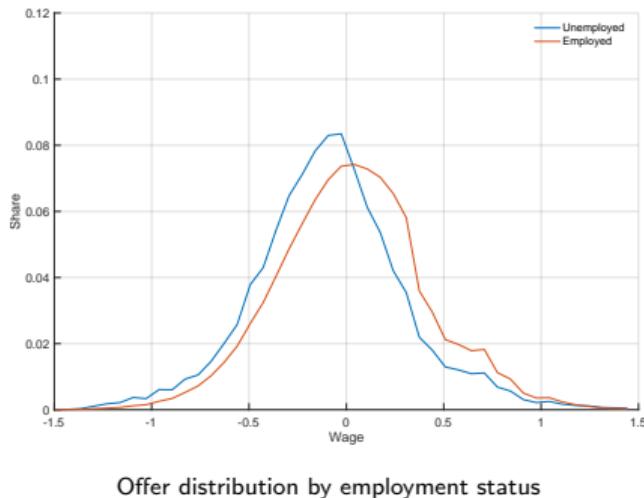

Decomposition of gap between offer and wage distributions

(1)	(2)	(3)	(4)
Overall gap	Job-to-job	Unobs. het.	On-the-job
0.104	39.6%	39.0%	33.2%

# The Employed Sample Better Job Offers

▶ back

- ▶ Faberman et al. (2024): employed get better offers
- ▶ Model replicates this through selection
- ▶ Pool of unemployed dominated by low type

## Employer Granularity From State-Year Panel

▶ back

- ▶ The # of LMs in state  $s$  in period  $y$ ,  $B_{sy}$ , is assumed proportional to the # of workers  $N_{sy}$

$$\beta = \frac{N_{sy}}{B_{sy}}.$$

That is, each market contains  $\beta$  workers

- ▶ It follows that the # of firms per market  $m_{sy}$  is

$$m_{sy} = \frac{M_{sy}}{B_{sy}} = \beta \frac{M_{sy}}{N_{sy}}.$$

- ▶ Then we can obtain a measure of the number of workers per market from

$$\ln \frac{\lambda_{sy}^e}{\lambda_{sy}} = \ln \left( 1 - \frac{fsize_{sy}}{\beta} \right) + \alpha_s + \alpha_y + \varepsilon_{sy}, \quad m_y = \frac{\beta}{fsize_y}$$

# Employer Granularity From State-Year Panel
